Acyclic nucleoside phosphonates (ANPs) belong to the most successful research topics in our Institute. Systematic investigations in this area resulted in three crucial antiviral drugs in medical practice: cidofovir, adefovir and tenofovir. Entering tenofovir and its therapeutic combinations (Truvada, Atripla, Complera, Stribild) to the market has the lion's share on transformation of HIV/AIDS from the life-threatening emergency to a manageable chronic disease.

Our present research in the field is targeted not only to synthesis of new structures but also to improvement of pharmacokinetic properties of compounds already known. There are dozens of therapeutically attractive ANP structures never advanced to the stage of preclinical/clinical investigations. These compounds have usually sufficient antiviral activity but very low bioavailability caused by their polar character. The way to overcome this problem is synthesis of prodrugs.

In this work, we present syntheses of various structural types of ANP prodrugs and comparison of their antiviral activities. These prodrugs are: amino acid ester phosphoramidates, POM and POC esters, alkyl and alkoxyalkyl esters, salicylic esters and (methyl-2-oxo-1,3-dioxol-4-yl) methylesters. We focus namely to two pharmacologically interesting ANP types: 2,4-diamino-6-[2-(phosphonomethoxy)ethoxy]pyrimidines— so-called “open-ring” derivatives and to the group of 5-azacytosine acyclic nucleoside phosphonates, especially 1-(*S*)-[3-hydroxy-2-(phosphonomethoxy)propyl]-5-azacytosine (HPMP-5-azaC) and 1-[2-(phosphonomethoxy)ethyl]-5-azacytosine (PME-azaC). HPMP-5-azaC and its cyclic form have been developed in our group as less toxic and more effective alternatives to cidofovir.

The prodrug form, hexadecyloxyethyl ester of cyclic HPMP-5-azaC revealed the highest values of anti-DNA virus activities including imposing selectivity indices on the order of thousands, e.g. 1160 for herpes simplex virus (HSV-1),  $\geq 5800$  for varicella zoster virus (VZV) or  $\geq 24600$  for human cytomegalovirus (HCMV). The only disadvantage of HPMP-5-azaC is its complicated metabolic profile due to instability of the 5-azacytosine ring in alkaline conditions including physiological pH. Comparing stability of various 5-azacytosine ANPs, we found much better stability for another 5-azacytosine derivative, 1-[2-(phosphonomethoxy)ethyl]-5-azacytosine (PME-azaC). Despite the fact that antiviral activity of this free phosphonic acid was only marginal we found promising antiviral activity in its prodrugs, especially against VZV and HCMV. It is another proof that some acyclic nucleoside phosphonates can increase their activities after transformation to prodrugs. Moreover, in some cases not only activity values but also the spectrum of activities could be influenced by transformation to prodrugs.

### Biography:

Dr. Marcela Krečmerová studied organic chemistry at Charles University in Prague and defended her PhD. thesis at the Institute of Organic Chemistry and Biochemistry (IOCB) of the Czech Academy of Sciences in 1990. Most of her scientific career she has been working in the field of nucleoside and nucleotide analogues, many years in a close collaboration with Professor Antonín Holý, the founder of acyclic nucleoside phosphonate chemistry. Her research in the field of 5-azacytosine compounds resulted in development of a new class of extraordinary active antivirals against DNA viruses. Recent investigations of Dr. Krečmerová are focused to development of prodrugs of biologically active molecules to improve their pharmacological properties and enable their future development as potential drugs. In 2012-2015 she was a head of the junior research team at the IOCB focused on development of novel therapeutics for cancer and viral diseases. She holds two patents and has co-authored 55 original scientific papers.
